

# MURUGA

## FULL STACK DEVELOPER, 4+

### Summary:

Full Stack Java Developer with 4+ years of experience in designing, developing, and maintaining enterprise-grade web applications using Java (11/17/21), Spring Boot, Angular, TypeScript, RESTful APIs, and relational databases. Experienced in building secure, scalable, and high-performance applications with Microservices architecture, CI/CD pipelines, and AWS cloud services. Strong background in Logistics and Supply Chain domain, API integration, Agile development, and cross-functional collaboration. Skilled in delivering responsive Angular applications and backend services with a focus on quality, performance, and maintainability.

---

### SKILLS

#### Frontend:

Angular (17), TypeScript  
JavaScript (ES6+),  
HTML5, CSS3,  
Bootstrap, Angular  
Material

#### Backend:

Java 11/17/21, Spring  
Boot, Spring MVC,  
Spring Data JPA,  
Hibernate, RESTful APIs,  
JSON,  
Swagger/OpenAPI,  
Spring, Security,  
OAuth2/JWT

**Database:** Oracle,  
PostgreSQL, SQL  
Server, MySQL,  
MongoDB

#### Cloud & DevOps:

AWS (EC2, S3, RDS,,  
IAM, CloudWatch),

### EXPERIENCE

#### WITQUALISTECHNOLOGIES PVT LTD

(CURRENTLY)

As Full Stack Developer

#### OTHER ORGANIZATION

Different Roles

### PROJECTS

**Project:** Multi-Chain Ethereum NFT Event Listener & Movement Tracking System

**Environment:** Rust, TypeScript, Ethereum, Polygon, BNB Chain, Arbitrum, Optimism, Axum, Node.js, Express, PostgreSQL, MongoDB, Docker, Kubernetes, GitHub Actions, Linux, CI/CD Pipelines, RabbitMQ, ethers-rs, web3.js, WebSockets, JSON-RPC APIs.

**Project Overview:** The platform was built to support multiple blockchain networks simultaneously, ensuring low-latency data processing, reliable event synchronization, and accurate NFT movement recording. Implemented optimized indexing, concurrent event listeners, and resilient retry mechanisms to handle high transaction volumes efficiently. The solution also included APIs and database services for querying NFT transaction history, wallet activities, and asset tracking analytics.

#### Role:

- Designed concurrent blockchain event listener architecture for multi-chain NFT monitoring.
- Developed smart contract event parsers for ERC-721 and ERC-1155 standards.
- Implemented real-time NFT transfer and ownership tracking pipelines.

Docker, Jenkins, Maven,  
Git, Azure DevOps  
Jira, CI/CD Pipelines

**Other:** Microservices  
Kafka, Event-Driven,  
Architecture, Agile,  
Scrum, Unit Testing,  
(JUnit, Mockito), API,  
Integration, Problem,  
Solving, Performance,  
Optimization

- Optimized event indexing and database performance for large-scale blockchain data.
- Built REST APIs for NFT activity retrieval and analytics.
- Integrated resilient retry, reorg handling, and fault-tolerant event processing mechanisms.
- Containerized services using Docker and deployed scalable workloads on Kubernetes.
- Automated deployments and testing workflows using GitHub Actions and CI/CD pipelines.
- Collaborated with cross-functional teams to enhance scalability, reliability, and blockchain data accuracy.

## EDUCATION

B.Tech 2021

### **Project: Posiedon**

**Environment:** Rust, RocksDB, Proof of Work (PoW), UTXO Model, Hashing, Cryptography, SHA-256, Serialization, CLI Utilities, Linux, Git

**Project Overview:** Developed “Poseidon,” a toy blockchain application in Rust to explore and understand the internal workings of blockchain systems. The project implemented a Proof of Work (PoW) consensus mechanism along with a UTXO-based transaction model similar to Bitcoin. Built core blockchain functionalities including block generation, mining, transaction validation, hashing, wallet handling, and chain verification. Integrated RocksDB for persistent storage and efficient blockchain data management. The project provided hands-on experience in distributed systems, cryptographic concepts, blockchain architecture, and low-level systems programming using Rust. **Role:**

- Designed and implemented blockchain data structures and block validation logic.
- Developed PoW-based mining and transaction verification mechanisms.
- Implemented UTXO-style transaction processing and wallet functionality.
- Integrated RocksDB for blockchain persistence and efficient storage management.
- Built cryptographic hashing and chain integrity validation features.
- Conducted testing and debugging to ensure blockchain consistency and reliability.
- Explored blockchain consensus models and distributed ledger concepts using Rust.

### **Project: Oak-log**

**Environment:** TypeScript, Deno, Oak Web Framework, Middleware Architecture, HTTP Logging, Git, Open Source Development, Linux, GitHub.

**Project Overview:** Developed “Oak-log,” an open-source plug-and-play logging library for the Oak web framework on Deno. The project was designed to simplify request and response logging for web applications by providing lightweight, customizable, and middleware-based logging functionality. Implemented structured logging, request tracing, status monitoring, response timing, and configurable log formats to improve debugging and

application observability. The library was built with performance and ease of integration in mind, enabling developers to seamlessly add centralized logging capabilities into Oak-based applications.

**Role:**

- Designed and developed reusable logging middleware for Oak applications.
- Implemented request/response logging, status tracking, and response time monitoring.
- Built configurable and extensible logging features for different application needs.
- Optimized middleware performance for lightweight and efficient execution.
- Managed open-source contributions, documentation, and GitHub repository maintenance.
- Performed testing, debugging, and version management for stable package releases.
- Collaborated with the developer community to improve usability and feature enhancements.

**Project:** Quicssh-rs

**Environment:** Rust, QUIC, HTTP/3, SSH, Async I/O, TCP/UDP Networking, Secure Tunneling, Tokio, Quinn, Rustls, Linux, Git, Docker.

**Project Overview:** Developed “Quicssh-rs,” a high-performance QUIC/HTTP3-based proxy solution for SSH connections using Rust. The project was designed to enable secure and efficient SSH communication over QUIC without requiring any server-side patching or modifications. Implemented low-latency proxying, encrypted transport handling, connection multiplexing, and reliable session forwarding using modern QUIC and HTTP/3 protocols. The solution improved connection stability, reduced latency, and enhanced network resilience compared to traditional TCP-based SSH communication. Focused on secure transport, asynchronous networking, and optimized systems-level performance using Rust.

**Role:**

- Designed and developed QUIC/HTTP3 proxy architecture for SSH traffic forwarding.
- Implemented asynchronous networking and secure encrypted communication pipelines.
- Integrated QUIC transport protocols for low-latency and multiplexed connections.
- Developed SSH session forwarding without requiring server-side modifications.
- Optimized proxy performance, connection stability, and resource utilization.
- Performed protocol testing, debugging, and network performance analysis.
- Managed code versioning, documentation, and deployment workflows using Git and Docker.
